Polygenic Traits

Polygenic traits are traits that are produced by two or more genes. The prefix “poly” means many and “genic” means genes.

Polygenic Traits

Human skin color is the result of four genes that interact to produce a large range of colors.

Human skin color is the result of four genes that interact to produce a large range of colors.

Polygenic Traits

Eye color is the result of the interaction of three genes with complicated patterns of expression. With eye color, green is dominant to blue, but recessive to brown.

Polygenic Traits

Height is a polygenic trait controlled by three genes. These genes determine how tall or short an offspring will become.

Polygenic Traits

Fur Color

two genes determine the general fur color, one gene effects shading, and one gene determines if the mouse is spotted

In animals, fur color is determined by multiple genes. In mice, two genes determine the general fur color, one gene effects shading, and one gene determines if the mouse is spotted. In some cases, a fifth gene can overshadow all of the other genes. This is called epistasis and can result in the mouse having albinism.

Polygenic Traits

Bell Curve

polygenic traits form a bell curve
when graphed

When the frequency of alleles in a population is graphed, polygenic traits always form a bell-shaped curve. The graph demonstrates that in polygenic traits, the intermediate phenotypes are seen in a higher frequency in a population than the extreme phenotypes.
